M68HC11 EEPROM  
Programming from  
a Personal Computer

## Introduction

This application note describes a simple and reliable method of programming either the M68HC11's internal EEPROM or the EEPROM connected to the MCU's external bus.

The data to be programmed is downloaded from any standard personal computer (PC) fitted with a serial communications port. In addition to the programming procedure, the software incorporates the facility to verify the contents of the MCU's internal or external memory against code held on a PC disc. Both program and verify options use data supplied in S record format, which is downloaded from the PC to the M68HC11 using the RS232 protocol supported by the MCU's SCI port.

The minimum MCU configuration required to program the M68HC11's internal EEPROM is shown in [Figure 1](#). This consists only of the MCU, an RS232 level-shifting circuit, plus an 8-MHz crystal and a few passive components.

Figure 1. M68HC11 Bootstrap Mode Connection to RS232 Line

To initiate the download, the PC is connected to the M68HC11 SCI transmit and receive lines via a level shifter. The circuit in [Figure 1](#) uses a Maxim MAX232 to eliminate the need for additional  $\pm 12$ -volt supplies. The MCU's special bootstrap mode is invoked by applying a logic 0 to the MODA and MODB pins, followed by a hardware reset.

Removing the reset condition causes the MCU to start execution of its bootloader program, located in internal ROM, between addresses \$BF40 and \$BFFF. In normal single-chip or expanded modes, the boot ROM is not accessible, and reads from these memory locations will result, respectively, in irrelevant data or external memory fetches.

An additional consequence of bootstrap operation is that all vectors are relocated to the boot ROM area. With the exception of the reset vector, which points to the start of the boot ROM, the remaining interrupt vectors all point to an uninitialized jump table in RAM. Three bytes are reserved for each entry in the jump table to allow for an extended jump instruction. [Table 1](#) and [Table 2](#) detail the memory map of the bootstrap vectors and an example RAM jump table.

**Table 1. Bootstrap Vector Assignments**

Address	Vector	Description
BFFE	BF40	Bootstrap reset
BFFC	00FD	Clock monitor
BFFA	00FA	COP fail
BFF8	00F7	Illegal opcode
BFF6	00F4	SWI
BFF4	00F1	XIRQ
BFF2	00EE	IRQ
BFF0	00EB	Real-time interrupt
BFEE	00E8	Timer output capture 1
BFEC	00E5	Timer output capture 2
BFEA	00E2	Timer output capture 3
BFE8	00DF	Timer output compare 1
BFE6	00DC	Timer output compare 2
BFE4	00D9	Timer output compare 3
BFE2	00D6	Timer output compare 4
BFE0	00D3	Timer output compare 5
BFDE	00D0	Timer overflow
BFDC	00CD	Pulse accumulator overflow
BFDA	00CA	Pulse accumulator input edge
BFD8	00C7	SPI
BFD6	00C4	SCI

Table 2. RAM Jump Table

Internal RAM	
Address	Typical Instruction
00FD	JMP CLKMON
00FA	JMP COPFL
. . . etc.	

**NOTE:** Before any interrupts are enabled in bootstrap mode, it is the software designer's responsibility to initialize all appropriate entries in the jump table.

As this application note does not make use of the M68HC11's interrupt system, the jump table is not set up.

The bootstrap program continues by initializing the SCI transmitter and receiver to 7812 baud and proceeds to examine the state of the NOSEC bit in the CONFIG register. If this is at logic 0 (security enabled), the bootloader will erase the entire contents of internal EEPROM and also the CONFIG register.

This feature is particularly useful for security-conscious applications, where the internal EEPROM contains information of a proprietary or confidential nature. If the NOSEC bit is at logic 1, then the erasing sequence is not carried out.

Note also that erasing the CONFIG register disables the security feature.

The bootstrap program then issues a break condition on the SCI transmit line and waits for the reception of the first byte. In this application, no use is made of the break transmitted by the SCI.

At this point, it is necessary to initiate the PC S record downloader program, called EELOAD.BAS (written in BASIC). It will display a header message and prompt the user for the number of the COM channel (either one or two) which is connected to the M68HC11. A listing of EELOAD.BAS is given at the end of this application note.

The PC-resident program will now configure the appropriate COM channel to 1200 baud, one stop bit, no parity, and download the binary file EEPROGIX.BOO from the PC to the M68HC11.

The M68HC11's bootloader automatically will detect the fact that the first incoming character is received at a different baud rate and change its SCI rate to 1200 baud.

It will then proceed to load the binary file into all 256 RAM locations and then jump to address \$0000 (for instance, the first RAM location).

EEPROGIX.BOO consists of the M68HC11 executable code shown in the source listing at the end of this application note, with the addition of \$FF at the head of the file, and \$00 appended up to the 256th byte. This program is designed to receive S records from the PC and program the data fields into the appropriate EEPROM memory locations.

A point to note is that the initial \$FF byte in EEPROGIX.BOO is only used to detect the baud rate of the PC and is not echoed back, while the remaining 256 bytes are echoed by the M68HC11's SCI transmitter. However, during download of EEPROGIX.BOO, the PC does not detect the echo, as this feature is unnecessary at this stage.

Once the newly downloaded S record programmer starts execution in the M68HC11, it configures the SCI to 9600 baud, then waits for a control character from the PC. This character will determine the operating mode of the S record programmer. The options available are shown in Table 3. Note that these programming utilities can be used to load and verify external RAM as well as external EEPROM.

**Table 3. S Record Downloader Operating Mode Options**

Control Character	Operating Mode
X	Program external EEPROM/RAM
I	Program internal EEPROM
V	Verify internal or external EEPROM/RAM

If the S record programmer has been downloaded successfully, the PC resident program will now:

1. Request whether the downloaded data must be echoed to the screen
2. Prompt the user for the required operating mode
3. Request the name of the S record file to be downloaded from the PC

Once the download starts, every character in the S record file is immediately echoed back to the PC. This ensures synchronism between the PC and the M68HC11, and at the same time it removes some of the overhead associated with the EEPROM programming delay time. It also removes the need for a hardware handshake.

---

## Verify Option

If a verify error occurs, the actual stored byte value is returned to the PC, where it is displayed with a preceding colon delimiter. In this way, EEPROM data and address faults can be quickly identified by inspection.

At the end of the verify download, the total number of errors is displayed.

---

## Internal or External Option

If a programming error occurs in either internal or external programming mode, for instance, if the read back data after programming does not correspond to the expected data, the M68HC11-resident software will hang up. This condition is detected by the PC-resident program, which will then abort the download and display an error message. This same error message is displayed if a fault or incorrect connection exists on the serial link between the PC and M68HC11.

The one exception to this operation stems from the fact that changes to the M68HC11's CONFIG register can be detected only after a subsequent hardware reset. If the CONFIG register address (\$103F) is detected, then the CONFIG register is not read directly after programming. This prevents premature termination of the download.

To allow programming of the CONFIG register in all mask set versions of the M68HC11A series and to permit expanded mode operation, the MCU resident program switches from bootstrap mode to special test mode by setting the MDA bit (bit 5) in the HPRIO register (address \$103C).

If the user wishes to maintain operation in bootstrap mode (to verify internal ROM code, for instance), then the BSET HPRIO,X,#MDA instruction on the eighth line of program code in EEPROGIX.ASC should be removed and the program reassembled.

---

## Programming Internal EEPROM

The techniques for programming internal and external EEPROM are quite different.

With internal EEPROM, it is first generally necessary to erase the required byte (erased state is \$FF) and follow with a write of data to the same address.

The internal programming sequence involves accessing the PPROG register (address \$103B) to latch the EEPROM address and data buses for the duration that the programming voltage is applied. Also, the programming time delay must be implemented or initiated by software. In this application, a software timing loop is used, but one of the internal M68HC11 timer functions could equally well be used to provide the time delay.

**Figure 2** and **Figure 3** show the flowcharts of the internal EEPROM erase and write sequences.

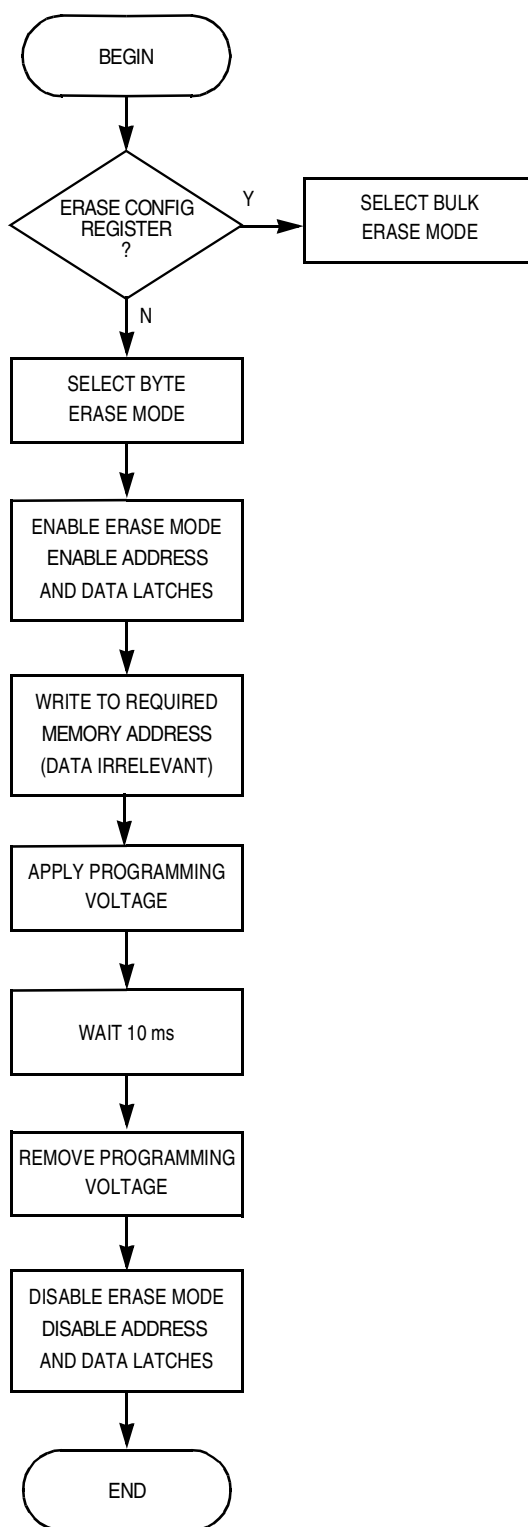

Figure 2. Internal EEPROM Erase Sequence

**Figure 3. Internal EEPROM Write Sequence**

---

## Programming External EEPROM

**Figure 4** shows the hardware needed to interface the M68HC11 to an external 2864 EEPROM, which provides a total of 8 Kbytes of reprogrammable memory. The addition of the MC68HC24 gives a minimal component count implementation of a circuit which accurately emulates the M68HC11A8 single-chip MCU. The added benefit of using the 2864 is that the software designer's program and/or data can be modified without removing the emulator from the target system. This can be particularly useful in applications where the emulator may be enclosed in a confined space or in an environmental chamber.

To program the 2864 from the PC, the external operating mode option (X) must be selected from the EELOAD menu.

Programming the 2864 involves fewer operations than are needed for internal EEPROM, as the former has no equivalent of the PPROG control register. In addition, the erase sequence and delay time are handled automatically by the 2864 on-chip logic.

A data polling technique is used to determine the end of the programming delay time. This involves examining the most significant bit of the data programmed by reading from the address just written to until the data becomes true. (During the programming delay time, the MS bit will read as the complement of the expected data.)

This means that the same software algorithm can be used to download code or data to external RAM as well as external EEPROM.

---

## Emulator Address Decoding

The emulator circuit in **Figure 4** shows the M68HC11's address line A13 connected to pin 26 of the 2864. Although this pin is actually unused by the 2864, its inclusion permits the replacement of the 2864 with a 27128 16-Kbyte EEPROM memory.

An important outcome of this is that, when a 2864 is used, the memory range \$C000-\$DFFF is mapped over the normally used 8-Kbyte range of \$E000-\$FFFF. In practice, this should never pose a problem. When a 27128 memory is used, its full 16-Kbyte address range of \$C000-\$FFFF is available to the MCU.

Included in the S record programmer, irrespective of the selected programming mode, is a feature to force program execution at the address specified in the S9 S record address field, provided the address is not \$0000.

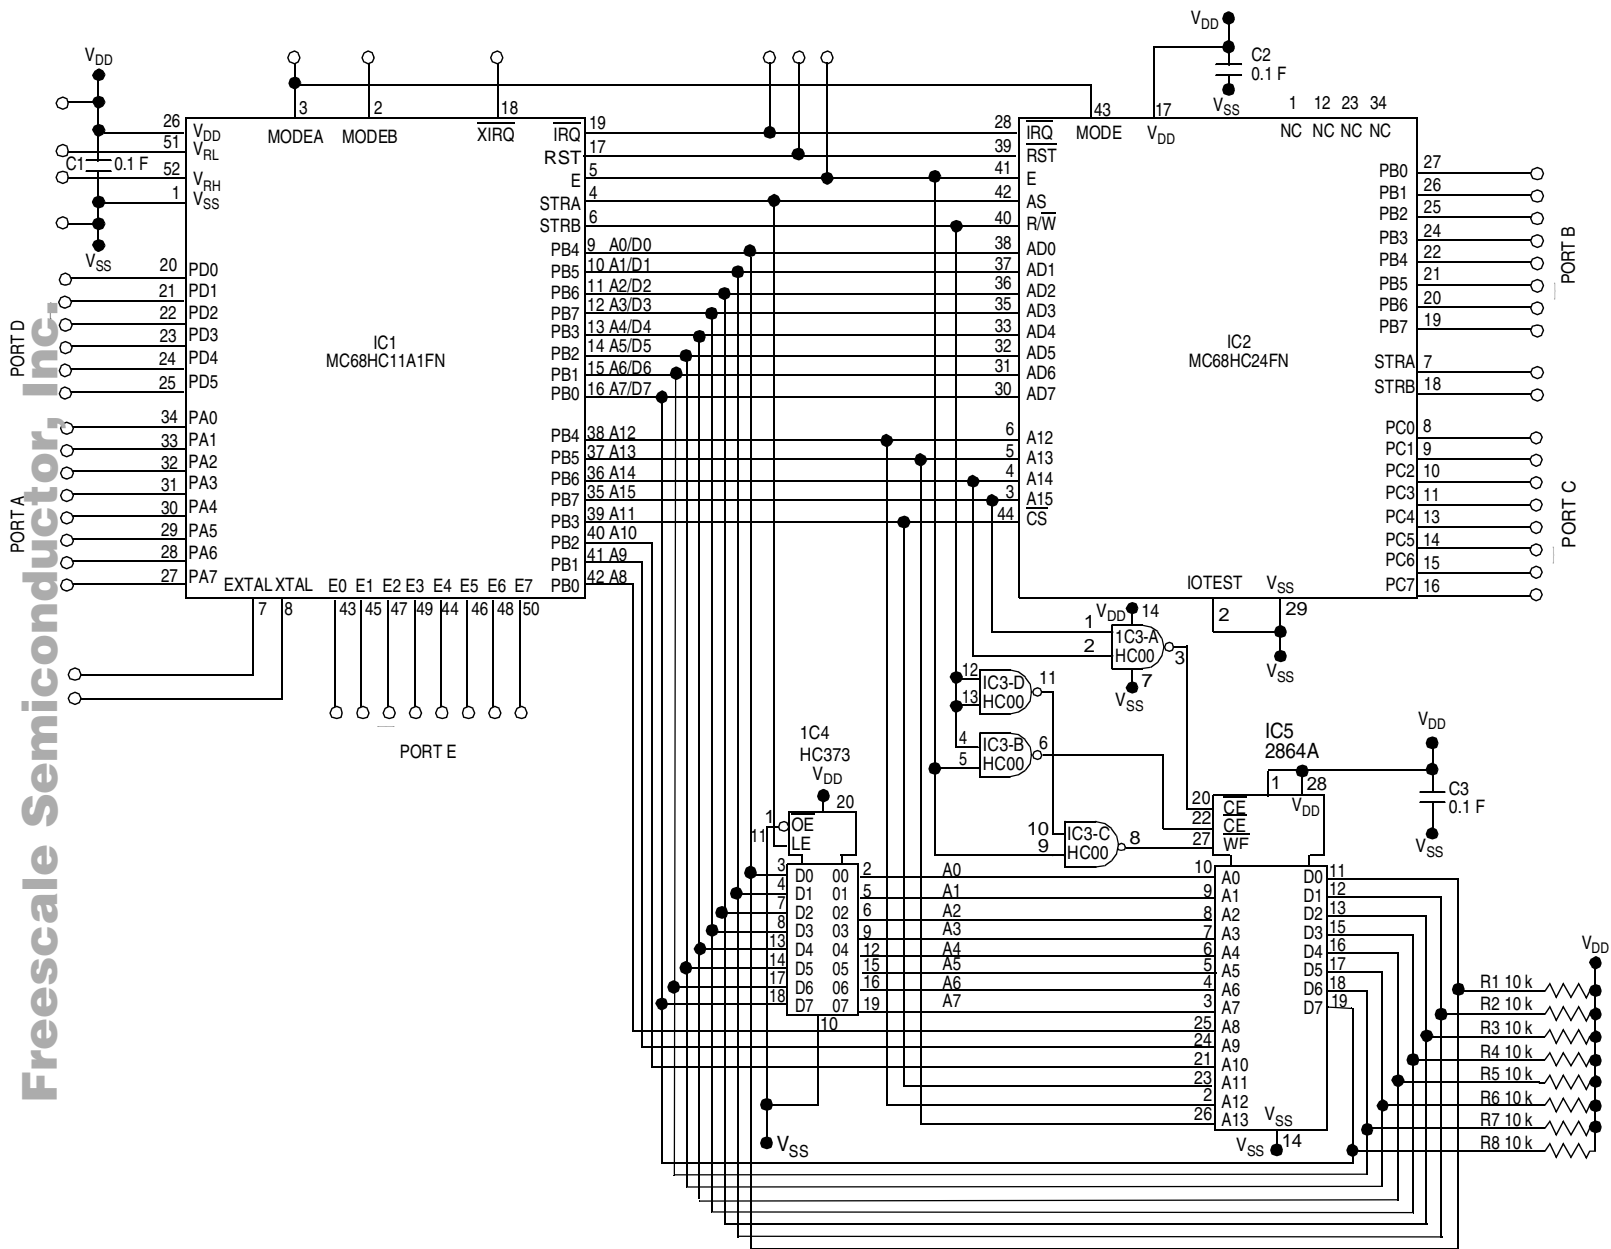

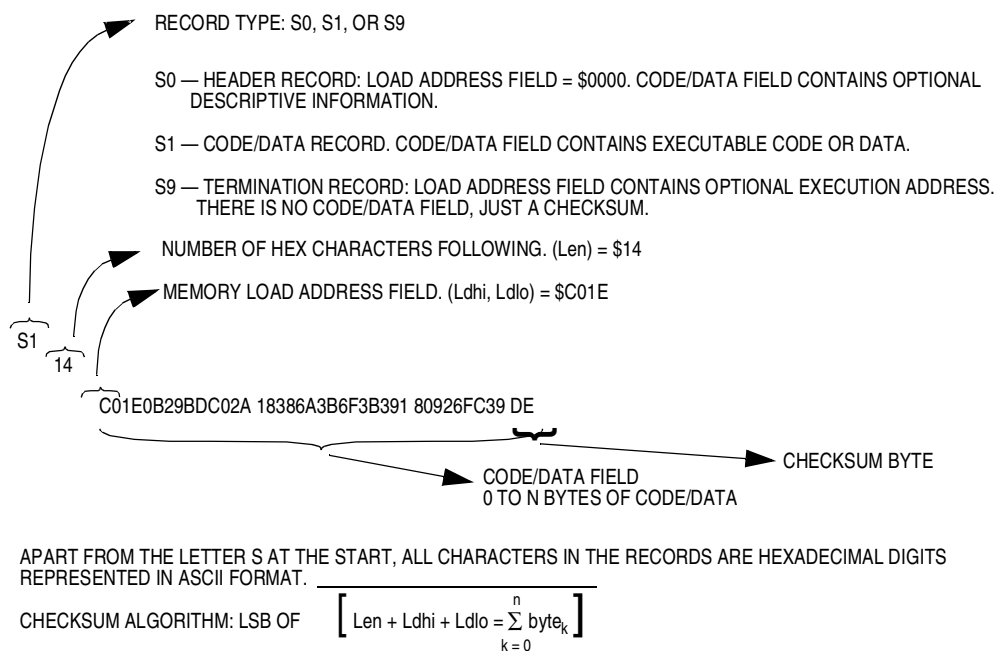

Figure 4. MC68HC11A8 Emulator Using 2864 EEPROM

Figure 5 shows the general format of S record files.

Note: The S record programmer in this application ignores the checksum byte.

Figure 5. S-Record Format

1 A      *****
2 A      *          EEPROMIX.ASC 19/3/87          Revision 1.0
3 A      *
4 A      * Written by R.Soja, Motorola, East Kilbride      *
5 A      * Motorola Copyright 1987.                      *
6 A      *
7 A      * This program loads S records from the host to      *
8 A      * either a 2864 external EEPROM on the 68HC11 external bus, *
9 A      * or to the 68HC11's internal EEPROM. It can also be used *
10 A     * verify memory contents against an S record file or just      *
11 A     * load RAM located on the 68HC11's external bus.          *
12 A     * Each byte loaded is echoed back to the host.          *
13 A     * When programming a 2864, data polling is used to detect*
14 A     * completion of the programming cycle. *
15 A     * As the host software always waits for the echo before *
16 A     * downloading the next byte, host transmission is suspended *
17 A     * during the data polling period.          *
18 A     * Because the serial communication rate (~1mS/byte) is *
19 A     * slower than the 2864 internal timer timeout rate (~300µs) *
20 A     * page write mode cannot be used. This means that data *
21 A     * polling is active on each byte written to the EEPROM, *
22 A     * after an initial delay of approx 500µs.          *
23 A     *
24 A     * When the internal EEPROM is programmed, instead of data *
25 A     * polling, each byte is verified after programming.      *
26 A     * In this case, the 500µs delay is not required and is *
27 A     * bypassed.          *

```

```

28 A      * If a failure occurs, the program effectively hangs up. It *
29 A      * is the responsibility of the host downloader program to *
30 A      * detect this condition and take remedial action.      *
31 A      * The BASIC program EELOAD just displays a 'Communication *
32 A      * breakdown' message, and terminates the program.      *
33 A      *
34 A      * When used in the verify mode, apart from the normal echo *
35 A      * back of each character, all differences between memory *
36 A      * and S record data are also sent back to the host.      *
37 A      * The host software must be capable of detecting this, and *
38 A      * perform the action required.      *
39 A      * The BASIC loader program EELOAD simply displays the *
40 A      * returned erroneous byte adjacent to the expected byte, *
41 A      * separated by a colon.      *
42 A      *
43 A      * Before receiving the S records, a code byte is received *
44 A      * from the host. i.e.:      *
45 A          ASCII 'X' for external EEPROM      *
46 A          ASCII 'I' for internal EEPROM      *
47 A          ASCII 'V' for verify EEPROM      *
48 A      *
49 A      * This program is designed to be used with the BASIC EELOAD      *
50 A      * program.      *
51 A      * Data transfer is through the SCI, configured for 8 data      *
52 A      * bits, 9600 baud.      *

119	A	0045	8D58	LOAD9	BSR	RDBYTE	Now discard remaining bytes,
120	A	0047	4A		DECA		including checksum.
121	A	0048	26FB		BNE	LOAD9	
122	A	004A	188C0000		CPY	#0	If execution address =0 then
123	A	004E	27FE		BEQ	*	hang up else
124	A	0050	186E00		JMP	,Y	jump to it!
125	A			*			
126	A		0053	LOAD1	EQU	*	
127	A	0053	8D4A		BSR	RDBYTE	Read byte count of S1 record into ACCB
128	A	0055	17		TBA		and store in ACCA
129	A	0056	8003		SUBA	#3	Remove load address & checksum bytes from count
130	A	0058	8D56		BSR	GETADR	Get load address into X register.
131	A	005A	1809		DEY		Adjust it for first time thru' LOAD2 loop.
132	A	005C	2017		BRA	LOAD1B	
133	A			*			
134	A	005E	D600	LOAD1A	LDAB	EEOPT	Update CC register
135	A	0060	2B25		BMI	VERIFY	If not verifying EEPROM then
136	A	0062	2705		BEQ	DATAPOLL	If programming external EEPROM
137	A	0064	C6A6		LDAB	#us500	
138	A	0066	5A	WAIT1	DECB		then wait 500us max.
139	A	0067	26FD		BNE	WAIT1	
140	A	0069	18E600	DATAPOLL	LDAB	,Y	Now either wait for completion of programming
141	A	006C	D803		EORB	<LASTBYTE	programming cycle by testing MS bit of last data written to
142	A	006E	D401		ANDB	<MASK	last data written to memory or just
143	A	0070	26F7		BNE	DATAPOLL	verify internal programmed data.
144	A	0072	4A	LOAD1E	DECA		When all bytes done,
145	A	0073	27B9		BEQ	LOAD	get next S record (discarding checksum)
146	A	0075	8D28	LOAD1B	BSR	RDBYTE	else read next data byte into ACCB.
147	A	0077	1808		INY		Advance to next load address
148	A	0079	7D0000		TST	EEOPT	
149	A	007C	2B05		BMI	LOAD1D	If verifying, then don't program byte!
150	A	007E	2743		BEQ	PROG	If internal EEPROM option selected then program
151	A	0080	18E700		STAB	,Y	else just store byte at address.

152 A 0083 D703	LOAD1D	STAB	<LASTBYTE	Save it for DATA POLLING operation.
153 A 0085 20D7		BRA	LOAD1A	
154 A	*			
155 A 0087 18E600	VERIFY	LDAB	,Y	If programmed byte
156 A 008A D103		CMP8	<LASTBYTE	is correct then
157 A 008C 27E4		BEQ	LOAD1E	read next byte
158 A 008E 8D08		BSR	WRITEC	else send bad byte back to host
159 A 0090 20E0		BRA	LOAD1E	before reading next byte.
160 A	*			
161 A 0092	READC	EQU	*	ACCA, X, Y regs unchanged by this routine.
162 A 0092 1F2E20FC		BRCLR	SCSR,X,#RDRF,*	
163 A 0096 E62F		LDAB	SCDR,X	Read next char
164 A 0098 1F2E80FC	WRITEC	BRCLR	SCSR,X,#TDRE,*	
165 A 009C E72F		STAB	SCDR,X	and echo it back to host.
166 A 009E 39		RTS		Return with char in ACCB.
167 A	*			
168 A 009F 8DF1	RDBYTE	BSR	READAC	1st read MS nibble
169 A 00A1 8D17		BSR	HEXBIN	Convert to binary
170 A 00A3 58		LSLB		and move to upper nibble
171 A 00A4 58		LSLB		
172 A 00A5 58		LSLB		
173 A 00A6 58		LSLB		
174 A 00A7 D702		STAB	<TEMP	
175 A 00A9 8DE7		BSR	READC	Get ASCII char in ACCB
176 A 00AB 8D0D		BSR	HEXBIN	
177 A 00AD DA02		ORAB	<TEMP	
178 A 00AF 39		RTS		Return with byte in ACCB
179 A	*			
180 A 00B0	GETADR	EQU	*	
181 A 00B0 36		PSHA		Save byte counter
182 A 00B1 8DEC		BSR	RDBYTE	Read MS byte of address
183 A 00B3 17		TBA		and put it in MS byte of ACCD
184 A 00B4 8DE9		BSR	RDBYTE	Now read LS byte of address into LS byte of ACCD
185 A 00B6 188F		XGDY		Put load address in Y
186 A 00B8 32		PULA		Restore byte counter
187 A 00B9 39		RTS		and return.
188 A	*			
189 A 00BA	HEXBIN	EQU	*	
190 A 00BA C139		CMP8	#'9	If ACCB>9 then assume its A-F
191 A 00BC 2302		BLS	HEXNUM	
192 A 00BE CB09		ADDB	#9	
193 A 00C0 C40F	HEXNUM	ANDB	#\$F	

194	A	00C2	39		RTS	
195	A			*		
196	A	00C3		PROG	EQU	*
197	A	00C3	36		PSHA	Save ACCA.
198	A	00C4	8616		LDAA	#\$16
199	A	00C6	188C103F		CPY	#CONFIG
200	A	00CA	2602		BNE	PROGA
201	A	00CC	8606		LDAA	#\$06
						bulk erase, to allow for A1 & A8 as well as A2.
202	A	00CE	8D10	PROGA	BSR	PROGRAM
203	A	00D0	8602		LDAA	#2
204	A	00D2	8D0C		BSR	PROGRAM
205	A	00D4	188C103F		CPY	#CONFIG
206	A	00D8	2603		BNE	PROGX
207	A	00DA	18E600		LDAB	,Y
						Load ACCB with old value, to prevent hangup later.
208	A	00DD	32	PROGX	PULA	Restore ACCA
209	A	00DE	20A3		BRA	LOAD1D
						and return to main bit.
210	A			*		
211	A	00E0		PROGRAM	EQU	*
212	A	00E0	A73B		STAA	PPROG,X
213	A	00E2	18E700		STAB	,Y
214	A	00E5	6C3B		INC	PPROG,X
215	A	00E7	3C		PSHX	Enable internal programming voltage
216	A	00E8	CE0D05		LDX	#mS10
217	A	00EB	09	WAIT2	DEX	and wait 10mS
218	A	00EC	26FD		BNE	WAIT2
219	A	00EE	38		PULX	
220	A	00EF	6A3B		DEC	PPROG,X
221	A	00F1	6F3B		CLR	PPROG,X
222	A	00F3	39		RTS	Disable internal programming voltage
223	A			*		Release internal addr/data latches
224	A				END	and return

### HOW TO REACH US:

#### USA/EUROPE/LOCATIONS NOT LISTED:

Motorola Literature Distribution;  
P.O. Box 5405, Denver, Colorado 80217  
1-303-675-2140 or 1-800-441-2447

#### JAPAN:

Motorola Japan Ltd.; SPS, Technical Information Center,  
3-20-1, Minami-Azabu Minato-ku, Tokyo 106-8573 Japan  
81-3-3440-3569

#### ASIA/PACIFIC:

Motorola Semiconductors H.K. Ltd.;  
Silicon Harbour Centre, 2 Dai King Street,  
Tai Po Industrial Estate, Tai Po, N.T., Hong Kong  
852-26668334

#### TECHNICAL INFORMATION CENTER:

1-800-521-6274
